## A1.1 Design of the anchoring equipment

A1.1.1 The anchoring equipment required herewith is intended for temporary mooring of a ship within a harbour or sheltered area when the ship is awaiting berth, tide, etc. IACS Recommendation No. 10 'Anchoring, Mooring and Towing Equipment' may be referred to for recommendations concerning anchoring equipment for ships in deep and unsheltered water.

A1.1.2 The equipment is therefore not designed to hold a ship off fully exposed coasts in rough weather or to stop a ship which is moving or drifting. In this condition the loads on the anchoring equipment increase to such a degree that its components may be damaged or lost owing to the high energy forces generated, particularly in large ships.

A1.1.3 The anchoring equipment required herewith is designed to hold a ship in good holding ground in conditions such as to avoid dragging of the anchor. In poor holding ground the holding power of the anchors is significantly reduced.

A1.1.4 The Equipment Number (EN) formulae for anchoring equipment as given in A1.2 and A1.3 are based on an assumed maximum current speed of 2.5 m/s, maximum wind speed of 25 m/s and a minimum scope of chain cable of 6, the scope being the ratio between length of chain paid out and water depth. For ships with an equipment length, as defined in Note 4 of A1.2, greater than 135 m, alternatively the required anchoring equipment can be considered applicable to a maximum current speed of 1.54 m/s, a maximum wind speed of 11 m/s and waves with maximum significant height of 2 m.

A1.1.5 It is assumed that under normal circumstances a ship uses only one bow anchor and chain cable at a time.

A1.1.6 Manufacture of anchors and anchor chain cables is to be in accordance with UR W29 and UR W18.

---

### Note:

1. Rev.5 of this UR is to be uniformly implemented by IACS Societies on anchors and anchor chain cables the manufacturing of which is commenced on or after 1 January 2007.
2. Rev.6 of this UR is to be uniformly implemented by IACS Societies on ships contracted for construction on or after 1 July 2018.
3. The "contracted for construction" date means the date on which the contract to build the vessel is signed between the prospective owner and the shipbuilder. For further details regarding the date of "contract for construction", refer to IACS Procedural Requirement (PR) No. 29.
4. Rev.7 of this UR is to be uniformly implemented by IACS Societies on ships contracted for construction on or after 1 January 2022.

# A1 (cont)

## A1.2 Equipment number and anchoring equipment table

A1.2.1 The equipment of anchors and chain cables for ships of unrestricted service is to be as given in Table 1 and is to be based on an 'Equipment Number' (EN) calculated as follows:

$$EN = \Delta^{\frac{2}{3}} + 2.0 (hB + S_{fun}) + \frac{A}{10}$$

where:

$\Delta$  = moulded displacement, in t, to the Summer Load waterline,

B = moulded breadth, in m,

h = effective height, in m, from the Summer Load waterline to the top of the uppermost house;

$$h = a + \sum h_i$$

a = vertical distance at hull side, in m, from the Summer Load waterline amidships to the upper deck at centreline,

$h_i$  = height, in m, on the centreline of each tier of houses having a breadth greater than B/4; for the lowest tier  $h_1$  is to be measured at centreline from the upper deck or from a notional deck line where there is local discontinuity in the upper deck, see figure below for an example,

$S_{fun}$  = effective front projected area of the funnel, in m<sup>2</sup>, defined as:

$$S_{fun} = A_{FS} - S_{shield}$$

$A_{FS}$  = front projected area of the funnel, in m<sup>2</sup>, calculated between the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the effective height  $h_F$ .

$A_{FS}$  is taken equal to zero if the funnel breadth is less than or equal to B/4 at all elevations along the funnel height.

$h_F$  = effective height of the funnel, in m, measured from the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the top of the funnel. The top of the funnel may be taken at the level where the funnel breadth reaches B/4.

$S_{shield}$  = the section of front projected area  $A_{FS}$ , in m<sup>2</sup>, which is shielded by all deck houses having breadth greater than B/4. If there are more than one shielded section, the individual shielded sections i.e  $S_{shield1}$ ,  $S_{shield2}$  etc as shown in figure 2 to be added together. To determine  $S_{shield}$ , the deckhouse breadth is assumed B for all deck houses having breadth greater than B/4 as shown for  $S_{shield1}$ ,  $S_{shield2}$  in figure 2.

A = side projected area, in m<sup>2</sup>, of the hull, superstructures, houses and funnels above the Summer Load waterline which are within the equipment length of the ship and also have a breadth greater than B/4. The side projected area of the funnel is considered in A when  $A_{FS}$  is greater than zero. In this case, the side projected area of the funnel should be calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height  $h_F$ .

# A1

(cont)

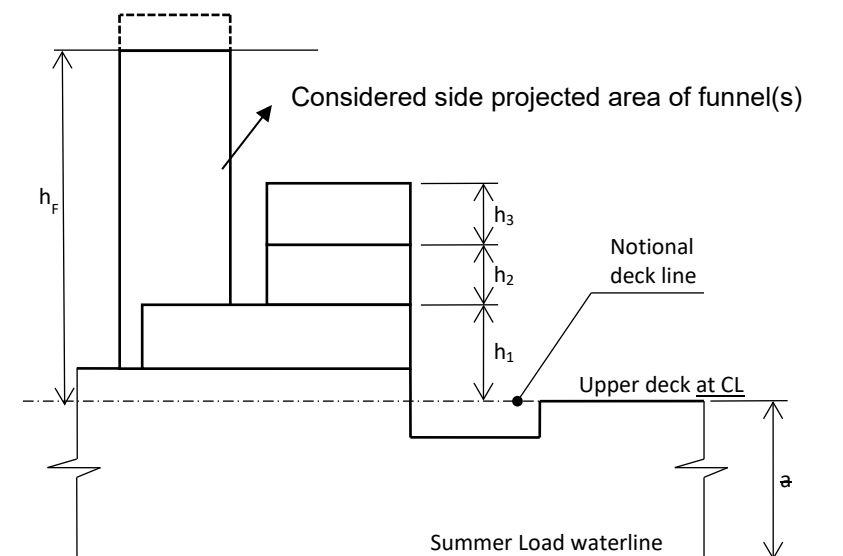

Figure 1

Figure 2

Notes:

1. When calculating  $h$ , sheer and trim are to be ignored, i.e.  $h$  is the sum of freeboard amidships plus the height (at centreline) of each tier of houses having a breadth greater than  $B/4$ .
2. If a house having a breadth greater than  $B/4$  is above a house with a breadth of  $B/4$  or less, then the wide house is to be included but the narrow house ignored.
3. Screens or bulwarks 1.5 m or more in height are to be regarded as parts of houses when determining  $h$  and  $A$ . The height of the hatch coamings and that of any deck cargo, such as containers, may be disregarded when determining  $h$  and  $A$ . With regard to determining  $A$ , when a bulwark is more than 1.5 m high, the area shown below as  $A_2$  is to be included in  $A$ .

# A1

(cont)

4. The equipment length of the ship is the length between perpendiculars but is not to be less than 96% nor greater than 97% of the extreme length on the Summer Load waterline (measured from the forward end of the waterline).
5. When several funnels are fitted on the ship, the above parameters are taken as follows:

$h_F$ : effective height of the funnel, in m, measured from the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the top of the highest funnel. The top of the highest funnel may be taken at the level where the sum of each funnel breadth reaches  $B/4$ .

$A_{FS}$ : sum of the front projected area of each funnel, in  $m^2$ , calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height  $h_F$ .

$A_{FS}$  is to be taken equal to zero if the sum of each funnel breadth is less than or equal to  $B/4$  at all elevations along the funnels height.

$A$ : Side projected area, in  $m^2$ , of the hull, superstructures, houses and funnels above the Summer Loadwaterline which are within the equipment length of the ship. The total side projected area of the funnels is to be considered in the side projected area of the ship,  $A$ , when  $A_{FS}$  is greater than zero. The shielding effect of funnels in transverse direction may be considered in the total side projected area, i.e., when the side projected areas of two or more funnels fully or partially overlap, the overlapped area needs only to be counted once.

A1.2.2 The total length of chain given in Table 1 - col. 4 - is to be divided in approximately equal parts between the two bower anchors.

A1.2.3 For ships of restricted service, the equipment is to be provided at the discretion of the Society.

\* Recommendations for ships with  $50 \leq EN < 205$  are given by IACS Recommendation No. 10.

**A1**  
(cont)**A1.3 Anchoring equipment for tugs and dredgers****A1.3.1 Equipment for tugs**

For tugs of unrestricted service the equipment is to be provided in compliance with the present requirement.

However, for determination of the Equipment Number, in the formula given in A1.2, the following may be substituted for the term  $2.0 hB$

$$2.0(aB + \sum h_i b_i)$$

where

a, B and  $h_i$  are defined in A1.2 and  $b_i$  is the breadth, in m, of the widest superstructure or deckhouse of each tier having a breadth greater than  $B/4$ .

For tugs of restricted service the equipment is to be provided at the discretion of the Society.

**A1.3.2 Equipment for dredgers**

For dredgers of unrestricted service having normal ship shape of underwater part of the hull the anchoring equipment is to be provided in accordance with this Unified Requirement.

When calculating the Equipment Number bucket ladders and gallows are not to be included. If however a dredger has unusual design of the underwater part of the hull, the Society is free to modify the requirements to anchoring equipment.

For dredgers of limited service, the equipment is to be provided at the discretion of the Society.

**A1.4 Anchors**

## A1.4.1 Types of anchors

## A1.4.1.1 Ordinary stockless anchors

- (a) Ordinary anchors of 'stockless' type are to be generally adopted and they are to be of appropriate design in compliance with the rules or practice of the Society.
- (b) The mass of the heads of stockless anchors including pins and fittings are not to be less than 60% of the total mass of the anchor.
- (c) The mass, per anchor, of bower anchor given in Table 1 is required for anchors of equal mass. The mass of individual anchors may vary to 7% of the Table mass provided that the total mass of anchors is not less than that required for anchors of equal mass.

## A1.4.1.2 High Holding Power (HHP) anchors

- (a) A 'high holding power' anchor is an anchor with a holding power of at least twice that of an ordinary stockless anchor of the same mass. A HHP anchor is to be suitable for ship's use and is not to require prior adjustment or special placement on the sea bottom.
- (b) When special type of anchors designated 'high holding power anchor' of proven superior holding ability are used as bower anchors, the mass of each anchor may be 75% of the mass required for ordinary stockless bower anchors in the Table 1.
- (c) For approval and/or acceptance as a HHP anchor satisfactory full scale tests according to A1.4.2 are to be made confirming that the anchor has a holding power of at least twice that of an ordinary stockless anchor of the same mass.

## A1.4.1.3 Super High Holding Power (SHHP) anchors

- (a) A 'super high holding power' anchor is an anchor with a holding power of at least four times that of an ordinary stockless anchor of the same mass. A SHHP anchor is suitable for restricted service ships' use and does not require prior adjustment or special placement on the sea bottom.
- (b) The use of SHHP anchors is limited to restricted service ships as defined by the Society.  
  
The SHHP anchor mass is generally not to exceed 1500kg.
- (c) The requirement for design of SHHP anchors applies down to  $EN \geq 205$ . For  $EN < 205$  the design criteria for SHHP anchors apply to the anchor mass given in Recommendation No. 10 for ordinary stockless anchors, reduced as permitted in accordance with 1.1 (c) of Recommendation No. 10.
- (d) When super high holding power anchors of the proven holding power are used as bower anchors, the mass of each such anchor may be reduced to not less than 50% of the mass required for ordinary stockless anchors in Table 1.
- (e) For approval and/or acceptance as a SHHP anchor satisfactory full scale tests according to A1.4.2 are to be made confirming that the anchor has a holding power of at least four times that of an ordinary stockless anchor or at least twice that of a previously approved HHP anchor of the same mass.

## A1.4.2 Anchor holding power tests for HHP and SHHP anchors

- (a) Full scale tests are to be carried out at sea on various types of bottom, normally, soft mud or silt, sand or gravel and hard clay or similar compounded material. The tests are to be applied to anchors of mass which are as far as possible representative of the full range of sizes proposed.
- (b) For a definite group within the range, the two anchors selected for testing (ordinary stockless anchor and HHP anchor, or ordinary stockless anchor and SHHP anchor, respectively) are to be of approximately the same mass and tested in association with the size of chain required for that anchor mass. Where an ordinary stockless anchor is not available, for testing of HHP anchors a previously approved HHP anchor may be used in its place. For testing of SHHP anchors, a previously approved HHP or SHHP anchor may be used in place of an ordinary stockless anchor. The length of the cable with each anchor is to be such that the pull on the shank remains horizontal. For this purpose a scope of 10 is considered normal but a scope of not less than 6 may be accepted. Scope is defined as the ratio of length of cable to depth of water.
- (c) Three tests are to be taken for each anchor and each type of bottom. The stability of the anchor and ease of breaking out are to be noted where possible. Tests are to be carried out from a tug but alternatively shore based tests may be accepted. The pull is to be measured by dynamometer. Measurements of pull, based on the RPM/bollard pull curve of the tug may be accepted as an alternative to a dynamometer.
- (d) For approval and/or acceptance for a range of HHP anchor sizes, tests are to be carried out for at least two anchor sizes. The mass of the maximum size approved is not to be more than 10 times the mass of the largest size tested.
- (e) For approval and/or acceptance for a range of SHHP anchor sizes, at least three anchor sizes are to be tested, indicative of the bottom, middle and top of the mass range.
- (f) The holding power test load is not to exceed the proof load of the anchor.

## A1.4.3 Installation of the anchors on board

The bower anchors are to be connected to their cables and positioned on board ready for use.

## A1.4.4 Proof testing of anchors

## A1.4.4.1 Testing of ordinary anchors

- (a) Anchors of all sizes are to be proof tested with the test loads stipulated in the Table 2.
- (b) The proof load is to be applied on the arm or on the palm at a spot which, measured from the extremity of the bill, is one-third of the distance between it and the centre of the crown, see figure below. In the case of stockless anchors, both arms are to be tested at the same time, first on one side of the shank, then reversed and tested on the other.
- (c) Before application of proof test load the anchors are to be examined to be sure that castings are reasonably free of surface imperfections of harmful nature. After proof load testing the anchors are to be examined for cracks and other defects. On completion of the proof load tests the anchors made in more than one piece are to be examined for free rotation of their heads over the complete angle. In every test the difference between the gauge lengths (as shown in figures) where one-tenth of the required load

# A1

(cont)

was applied first and where the load has been reduced to one-tenth of the required load from the full load may be permitted not to exceed 1%.

Stocked Anchor

Stockless Anchor

#### A1.4.4.2 Testing of HHP anchors

The HHP anchor is to be proof tested with load required by Table 2 for an anchor mass equal to 1.33 times the actual mass of the HHP anchor. The proof loading procedure and examination procedure for HHP anchors are to comply with those for ordinary anchors, A1.4.4.1 (b) and (c).

#### A1.4.4.3 Testing of SHHP anchors

- (a) The SHHP anchor is to be proof tested with the load required by Table 2 for an anchor mass equal to twice the actual mass of the SHHP anchor. The proof loading procedure and examination procedure for SHHP anchors are to comply with those for ordinary anchors, A1.4.4.1 (b) and (c).
- (b) After the proof load test, all SHHP anchors are to be surface inspected by the dye penetrant method or by the magnetic particle method. All surfaces of cast steel anchors are to be surface inspected. All cast steel anchors are to be examined by UT in way of areas where feeder heads and risers have been removed and where weld repairs have been carried out. The surface inspections and UT inspections are to follow Recommendation No. 69 'Guidelines for NDE of Marine Steel Castings'. Welded steel anchors are to be inspected at the welds. At sections of high load or at suspect areas, the Society may impose volumetric non-destructive examination, e.g, ultrasonic inspection or radiographic inspection.
- (c) At the discretion of the Society, additional tests of the anchor may be required. These tests include the hammering test and the drop test, and are usually applied to cast steel anchors.

## A1.4.5 SHHP anchor material selection and toughness

All SHHP anchors are to be manufactured from materials meeting the requirements of the IACS URs as follows:

Welded Steel Anchors:	UR W11	Normal and Higher Strength Hull Structural Steel
	UR W17	Approval of consumables for welding normal and higher strength hull structural steel
Cast Steel Anchors:	UR W8	Hull and machinery steel castings
Anchor Shackles:	UR W7	Hull and machinery steel forgings
	UR W8	Hull and machinery steel castings

The base steel grades in welded SHHP anchors are to be selected with respect to the material grade requirements for Class II of S6.1 in UR S6 'Use of steel grades for various hull members'. The welding consumables are to meet the toughness for the base steel grades in accordance with UR W17 'Approval of consumables for welding normal and higher strength hull structural steel'. The toughness of the anchor shackles for SHHP anchors is to meet that for Grade 3 anchor chain in accordance with UR W18 'Anchor chain cables and accessories'. The toughness of steel castings for SHHP anchors is to be not less than a Charpy-V notch energy average of 27 J at 0 degree C.

## A1.4.6 Fabricated anchors

Fabricated anchors are to be manufactured in accordance with approved welding procedures using approved welding consumables and carried out by qualified welders.

**A1.5 Chain cables for bower anchors****A1.5.1 Anchor chain cable design**

A1.5.1.1 The anchor chain cable is to be as required by Table 1 for the calculated Equipment Number for the ship. The chain cable is to be tested in accordance with Table 5 to the proof loads corresponding to those for the required chain cable.

A1.5.1.2 Wire rope may be used in place of chain cable on ships with less than 40 m in length and subject to the following conditions:

- (a) The length of the wire rope is to be equal to 1.5 times the corresponding tabular length of chain cable (col. 4 of Table 1) and their strength is to be equal to that of tabular chain cable of Grade 1 (Table 4).
- (b) A short length of chain cable is to be fitted between the wire rope and anchor having a length of 12.5 m or the distance between anchor in stowed position and winch, whichever is less.
- (c) All surfaces being in contact with the wire need to be rounded with a radius of not less than 10 times the wire rope diameter (including stem).

A1.5.1.3 For restricted services the use of steel wire rope may be accepted in place of chain cable at the discretion of the Society.

**A1.5.2 Grades of chain cables**

Bower anchors are to be associated with stud link chain cables for one of the grades listed in Table 3.

**Table 3 Grades of chain cables**

Material	Grade	Range of UTS (N/mm <sup>2</sup> )
Mild steel	1	300 to 490
Special quality steel	2	490 to 690
Extra special quality steel	3	> 690

*Note:*

*The designation 'Grade 1' may be replaced, at discretion of the Society, by 'Grade 1a' where UTS is greater than 300 but not exceeding 400 N/mm<sup>2</sup> or by 'Grade 1b' where UTS is greater than 400 but not exceeding 490 N/mm<sup>2</sup>.*

**A1.5.3 Proof and breaking loads of stud link chain cables**

- (a) The design and/or standard breaking loads (BL) and proof loads (PL) of stud link chain cables are given in Table 4 for the chain diameter, d, in mm.
- (b) The test load values, rounded off from the loads in (a) above to be used for testing and acceptance of chain cables, are given in Table 5.

A1  
(cont)

Table 4 Breaking loads and proof loads of stud link chain cables

Grade	BL (kN)	PL (kN)
1	$BL_1 = 9.80665 \cdot 10^{-3} [d^2(44 - 0.08 d)]$	$PL_1 = 0.7 BL_1$
2	$BL_2 = 1.4 BL_1$	$PL_2 = BL_1$
3	$BL_3 = 2 BL_1$	$PL_3 = 1.4 BL_1$

## A1.6 Permissible wear down of stud link chain cable for bower anchors

When a length of chain cable is so worn that the mean diameter of a link, at its most worn part, is reduced by 12% or more from its required nominal diameter it is to be renewed.

The mean diameter is half the value of the sum of the minimum diameter found in one cross-section of the link and of the diameter measured in a perpendicular direction in the same cross-section.

## A1.7 Supporting hull structures of anchor windlass and chain stopper

The supporting hull structure of anchor windlass and chain stopper is to be sufficient to accommodate the design and sea loads.

### A1.7.1 Design loads

The design loads are to be taken not less than:

- for chain stoppers, 80% of the chain cable breaking load
- for windlasses, where no chain stopper is fitted or the chain stopper is attached to the windlass, 80% of the chain cable breaking load
- for windlasses, where chain stoppers are fitted but not attached to the windlass, 45% of the chain cable breaking load

The design loads are to be applied in the direction of the chain cable.

**A1**  
(cont)

## A1.7.2 Sea loads

The sea loads are to be taken according to UR S27.

## A1.7.3 Permissible stresses

The stresses acting on the supporting hull structures of windlass and chain stopper, based on net thickness obtained by deducting the corrosion addition,  $t_c$ , given in A1.7.4, are not to be greater than the following permissible values:

(a) For strength assessment by means of beam theory or grillage analysis:

- Normal stress:  $1.0 R_{eH}$
- Shear stress:  $0.6 R_{eH}$

The normal stress is the sum of bending stress and axial stress. The shear stress to be considered corresponds to the shear stress acting perpendicular to the normal stress. No stress concentration factors are to be taken into account.

(b) For strength assessment by means of finite element analysis:

- Von Mises stress:  $1.0 R_{eH}$

For strength assessment by means of finite element analysis the mesh is to be fine enough to represent the geometry as realistically as possible. The aspect ratios of elements are not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs must not exceed one-third of the web height. In way of small openings in girder webs, the web thickness is to be reduced to a mean thickness over the web height as per individual Class Society rules. Large openings are to be modelled. Stiffeners may be modelled using shell, plane stress, or beam elements. The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modeled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.

$R_{eH}$  is the specified minimum yield stress of the material.

## A1.7.4 Corrosion addition

The total corrosion addition,  $t_c$ , is not to be less than the following values:

(a) Ships covered by Common Structural Rules for Bulk Carriers and Oil Tankers:

$t_c$ : total corrosion addition as defined in these rules.

(b) Other ships:

For the supporting hull structure, the total corrosion addition,  $t_c$ , is defined according to the Society's Rules for all considered structural members used in the model (e.g. deck structures).
